INL cyber researchers use cutting-edge techniques and tools to help reduce critical infrastructure

vulnerabilities.

Cyber Vulnerability Assessments

daho National Laboratory's Cybercore Integration Center employs an elite team of cyber and control systems researchers and engineers who conduct in-depth vulnerability assessments of equipment common across all critical infrastructure sectors. Our work helps identify vulnerabilities and provides analysis and assessments so utility owners, operators and vendors can improve their defenses, operational efficiency, network reliability and security.

Vulnerability assessments help illuminate weaknesses within equipment, alerting both manufacturers and end users to the potential need for additional protection strategies, mitigation research or patch development. Working with a broad range of private industries, government organizations, vendors and manufacturers to develop techniques and tools, INL researchers help reduce the cyber vulnerabilities found in many of the nation's critical infrastructures. To protect proprietary information, the laboratory has established cooperative research agreements and nondisclosure agreements with dozens of companies and works regularly with others who have expressed interest in the lab's capabilities.

METHODOLOGY

Cybercore researchers use a rigorous methodology to analyze and test control system components including:

Setup Equipment

Upon receipt of equipment from a manufacturer, the assessment team will set it up to operate as intended in the field. This includes acquiring configuration, management and monitoring software, as well as use and setup documentation.

Conduct Teardown

During this step, INL researchers disassemble equipment to the board level, exposing and removing all circuit boards from the unit. Researchers photograph progress to thoroughly document their activities, pull datasheets for all identified components, and confirm all communication ports.

Pull Firmware

Nonvolatile memory integrated circuits (ICs) and microcontrollers are of special interest during teardown. From these components, researchers attempt to pull the unit's firmware via on-board, in-circuit programming headers, pulling ICs from the board, or by observing a firmware update, and note any observed protections or encryptions.

Analyze Firmware

protocol type.

the bus and communication

Researchers assess firmware for vulnerabilities by either reviewing vendor-provided source code or pulling binaries from the system. Then, they analyze buffer overflow vulnerabilities, password or key encryption, coding practices, open ports or unused peripherals, undisclosed wireless interfaces, software backdoors, and potential use of the device as an access point.

Black Box Approach

Simultaneous to the teardown and firmware analysis, researchers conduct a parallel effort to determine vulnerabilities by treating equipment as a black box. In other words, assuming no physical access, what information can be ascertained about this system, and can it possibly be compromised? This analysis primarily includes equipment that is connected to a network via wired or wireless means.

Report Findings

Finally, researchers report device and network vulnerabilities discovered during the firmware analysis and black box assessment to the manufacturer. Security assessments of equipment are kept confidential. Reports generated in cooperation with industry or government agencies are provided only to the sponsoring organization or manufacturer. These assessments play a vital role in identifying and correcting potential vulnerabilities that could be exploited by adversaries.
